

Low-Power Beam Splitter Principle

Overview

Beamsplitters enable complex light manipulation across diverse scientific and industrial fields, underpinning numerous advanced optical systems. The physical mechanism for dividing a light beam relies on partial reflection and partial transmission at a specially treated optical. A beam splitter (or beamsplitter, power splitter) is an optical device which can split an incident light beam (e. a laser beam) into two (or sometimes more) beams, which may or may not have the same optical power (radiant flux). It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. This division allows for the simultaneous analysis or utilization of the light's properties along two separate paths. Electric elds E1 and E2 enter input ports 1 and 2.
